Do wind turbine blades rotate clockwise?

All current-day wind-turbine blades rotate in clockwise direction as seen from an upstream perspective. The choice of the rotational direction impacts the wake if the wind profile changes direction with height. Here, we investigate the respective wakes for veering and backing winds in both hemispheres by means of large-eddy simulations.

How does a wind turbine generator work?

In a wind turbine generator, propeller-like blades spin around a rotor, spinning a generator, which creates electricity. As the wind blows across the rotor blades, a pressure gradient is formed between the upwind and downwind sides of the blade causing a resulting lifting force which pushes the blades clockwise around the main shaft.

Does a generator care which direction it rotates?

The generator doesn't care which direction it rotates--the only thing that matters is how the output leads are connected to the breaker that will close when the unit (prime mover and generator) is being synchronized to the grid with other prime movers and generators.

Why does a wind turbine wake rotate opposite to a turbine blade?

The wake rotates opposite to the blade rotation due to aerodynamics and design of the wind-turbine blades (Zhang et al., 2012). In contrast, the rotational direction of the far wake is determined by the Ekman spiral.

Should veering blades be counterclockwise rotating?

This work suggests that counterclockwise-rotating blades in the case of veering inflow and clockwise-rotating blades in the case of backing inflow in the NH (and vice versa in the SH) could have benefits as well. The wake deflection angle becomes larger if the spanwise flow component is amplified by the vortex induced by the rotating wind turbine.

How does wind affect rotating blades?

Rotating blades encounter a variety of wind conditions. In a convective regime during the daytime above the surface layer, there is no significant change in the incoming wind direction or wind speed with height and the inflow conditions are uniform over the whole rotor area.
