Do DC microgrids require advanced protection techniques for fault detection and isolation?

Abstract: DC microgrids require advanced protection techniques for fault detection and isolation(FDI). In this work, an FDI method able to respond to different types of component faults is developed based on system modeling. First, the state-space representation of a multiterminal dc microgrid with component faults is derived.

How effective is FDI method for detecting faults in DC microgrids?

The performance of the proposed FDI method is verified under the real-time (RT) simulation of a three-terminal low-voltage dc microgrid and with a small-scale laboratory dc grid. The proposed FDI method is proved to be effective detect and isolate different faults in dc microgrids with a response time of 1 ms.

How can FDI be used in a multiterminal DC microgrid?

First, the state-space representation of a multiterminal dc microgrid with component faults is derived. Then, an FDI function based on observers is designed. To achieve the desired selectivity in fault isolation, the linear matrix inequality (LMI) optimization approach is adopted in the observer design.

How do we evaluate a microgrid?

Our researchers evaluate in-house-developed controls and partner-developed microgrid components using software modeling and hardware-in-the-loop evaluation platforms. A microgrid is a group of interconnected loads and distributed energy resources that acts as a single controllable entity with respect to the grid.
