Can Inlet air temperature improve gas turbine efficiency?

The results show that an increase in inlet air temperature has considerable potential for improving gas turbine efficiency due to the increase in compressor and turbine efficiency. This finding is different from traditional viewpoints. Meanwhile, each partial load has an optimum heating temperature which becomes higher when the load is lower.

Does an inlet air cooling system improve power output and efficiency?

Still, the results indicate that the power output and efficiency of the gas turbine improved as long as the ambient temperature remained at their lower values. Because of this, the incorporation of an inlet air cooling system could mitigate the negative influence of high temperatures in tropical locations.

What are the requirements for a gas turbine inlet temperature regulator?

The gas turbine inlet temperature regulator has strict requirements for the resistance of the air flow outside the tube. Generally, the operating resistance is required to be controlled below 150 Pa, which requires that the air flow speed should not be too high.

Does changing turbine inlet temperature increase net power?

For this purpose, based on the energy, exergy, environmental, and economic (4E) analyses, the effects of changing turbine inlet temperature (TIT) on a gas turbine power plant in northeastern Iran were studied. The results showed that increasing TIT enhanced net power and efficiency, so that increasing TIT about 10 K enhanced net power by 1.7%.

Does inlet air temperature affect power to heat ratio?

Integrating the GT with HRSG to generate steam for power generation and process heat tends to increase energy utilization factor of the system at elevated inlet air temperatures. Increasing inlet air temperature plays a negative impact on power to heat ratio (PHR), while relative humidity has no effect on PHR.

How much power does a gas turbine lose if ambient temperature rises?

An ambient temperature of 37 °C caused an average power loss of 17%, accompanied by an efficiency drop of 2.2% compared to the gas turbine design value. Actual data shows that the gas turbine lost 0.1% in thermal efficiency and 1.47 MW of its power output for every °C rise in ambient temperature above ISO conditions.

Increased ambient temperature lowers the density of the inlet air, thus reducing the mass flow through the turbine, and therefore reduces the power output (which is proportional to the mass flow) even further.

The fuel may reach the engine at an excessive temperature, and combustion will not take place in adequate conditions. The efficiency of the cooling system will be diminished. As a result, if the radiator is not correctly ...
