

## Wind turbine power generation wind farm boundary legend

Are 'fully developed wind turbine array boundary layers' suitable for wind farms?

It is also important to point out that the current findings are relevant to optimal spacing in the 'fully developed wind turbine array boundary layer' for wind farms that are significantly larger than the fetch required for a surface disturbance to reach equilibrium with the entire ABL.

How do wake interactions affect power generation in a wind farm?

In a wind farm, the wake interactions of wind turbines could significantly affect the overall power generation because the huge wake expansion of an upstream turbine reduces the energy capture of a downstream turbine in an array.

Why do wind farms have turbulent flow conditions?

Wind farms have very turbulent flow circumstances because the upstream turbines' wake affects the inflow of the turbines located farther downstream. As a result of these wake interferences across several wind turbines, the output power performance of a wind farm may be significantly reduced.

Does turbulence model predict higher power generation in wind farms?

Sometimes, the RANS model forecasts higher power generation in wind farms than the LES model because the wake decays faster, but this behavior strongly depends on the chosen turbulence model in RANS. The present study reviews the flow around onshore wind turbines in different terrain features.

What are boundary turbines in a wind farm?

The boundary turbines are spaced around the circumference of the wind farmand are defined with one design variable. The rest of the turbines in the farm make up the inner grid, which is defined with four design variables for a total of five variables to describe the location of every turbine in the farm.

## How much power does a wind farm have?

With the rapid increase in total installations, the development of wind turbine technology, and decrease in the levelised cost of energy (LCOE), the turbine density in wind farms has continuously increased. The mean installed power densities of onshore and offshore turbines are approximately 20 MW/km 2 and 7.2 MW/km 2 , respectively.

We find that the pronounced wind veer in stably stratified boundary layers creates asymmetry in the available wind resource, which can only be studied in finite-size wind farm simulations. We emphasize that ...
